

**6331 - Algorithms, Autumn 2016, CSE, OSU**

**Homework 7**

**Instructor:** Anastasios Sidiropoulos

**Problem 1.** In a binary min-heap with  $n$  elements, both the INSERT and EXTRACT-MIN operations take  $O(\log n)$  worst-case time. Give a potential function  $\Phi$  and prove that using  $\Phi$ , the amortized cost of INSERT is  $O(\log n)$  and the amortized cost of EXTRACT-MIN is  $O(1)$ .

**Problem 2.** For any integer  $n > 1$ , give a sequence of operations performed on an empty Fibonacci heap  $H$ , such that the resulting heap contains a single tree that is a linear chain of  $n$  nodes (that is, a tree with  $n$  nodes, and of height  $n - 1$ ).

**Problem 3.** We are interested in designing a data structure for maintaining a set  $A$  of integers, that supports the following operations:

- $\text{Insert}(A, x)$ : Insert the integer  $x$  into the set  $A$ .
- $\text{ApproximateMedian}(A)$ : Return some  $x \in A$  such that at least 25% of the elements in  $A$  are not greater than  $x$  and at least 25% of the elements in  $A$  are not smaller than  $x$ .

You may assume that the data structure starts with the set  $A$  being empty.

- (a) Design a data structure for the above problem using a balanced binary search tree, with worst-case query time  $O(\log n)$ .
- (b) Design a data structure for the above problem using an array, with amortized time per query  $O(\log n)$ .
